This report includes the most commonly used Forest Inventory and Analysis statistics. However, additional forest resource data can be provided to interested users. Persons requesting additional information that can be provided from the raw inventory data are expected to pay the retrieval costs. These costs range from less than \$100 for a relatively simple request to \$2,000 for a complex retrieval involving the services of a Forest Inventory and Analysis computer programmer. Requests will be filled so as to minimize the impact on the Forest Inventory and Analysis Work Unit.

Requests for unpublished information may be directed to:

FOREWORD

Forest Inventory and Analysis (FIA) is a continuing endeavor as mandated by the Renewable Forest and Rangeland Resources Planning Act of 1974. Prior inventories were mandated by the McSweeney-McNary Forest Research Act of 1928. The objective of FIA is to periodically inventory the Nation's forest land to determine its extent, condition, and volume of timber, growth, and depletions. Up-to-date resource information is essential to frame intelligent forest policies and programs. USDA Forest Service regional experiment stations are responsible for conducting these inventories and publishing summary reports for individual States. The North Central Forest Experiment Station is responsible for forest resource evaluation in Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, South Dakota, and Wisconsin.

Fieldwork for the Missouri statewide forest inventory was begun in January 1987 and completed in June 1989. Reports on the three previous inventories of Missouri's timber resource are dated 1947, 1959, and 1972.

More accurate survey information was obtained during the 1989 survey than otherwise would have been feasible because of intensified field sampling. Such sampling was made possible by additional funding provided by the Missouri Department of Conservation. The Department also surveyed primary wood-using plants in the State. Data from this survey were used to help estimate the quantity of timber products harvested in the State. Missouri Department of Conservation personnel have also assisted in training field personnel, analyzing information obtained from the survey, and preparing this report.

Aerial photos used in the Missouri Forest Inventory were furnished by the USDA Agricultural Stabilization and Conservation Service and the Missouri Department of Natural Resources Geology and Land Survey.

HIGHLIGHTS

NOTE: *Data from new forest inventories are often compared with data from earlier inventories to determine trends in forest resources. However, for the comparisons to be valid, the procedures used in the two inventories must be similar. As a result of our ongoing efforts to improve the efficiency and reliability of the inventory, several changes in procedures and definitions have occurred since 1972. Because some of these changes will make it inappropriate to directly compare the 1989 data with those published for 1972, data from the 1972 inventory will be reprocessed using the 1989 procedures and will be published in part in the State statistical report. Please refer to the Appendix section labeled "Comparing Riverborder Fourth Inventory with the Third Inventory" for more details.*

General

The Riverborder Survey Unit is a strip of 22 counties adjacent to the Missouri and Mississippi Rivers (see cover). It contains 8 million acres or 18 percent of Missouri's land area.

Because proximity to the two major rivers encouraged early settlement and rapid development, it is not surprising that half of the State's population resides here. However, most of the people are concentrated in the highly industrialized area around St. Louis. Outside the St. Louis metropolitan area, the region is predominantly rural.

Mark H. Hansen, Research Forester, received a B.S. degree in Forest Science from the University of Minnesota in 1976, an M.S. degree in Forest Biometry from the University of Wisconsin-Madison in 1977 and a Ph.D. degree in Forest Biometry from the University of Minnesota in 1990. He joined the Forest Service in 1978, and has been working with North Central's Forest Inventory and Analysis Unit since 1979.

The Riverborder can be divided into two distinct subregions. North of Scott County lies a network of rolling river hills and bluffs dissected by numerous tributary streams and drainages. This is the beginning of the Ozark hills to the south and west. In counties along the Missouri River, the transition from level prairie on the north to the Ozarks on the south can be seen. From Scott County southward, the topography is quite different. This area, known as the Bootheel, is the northern extremity of the Mississippi Alluvial Plain that extends south through Arkansas and Louisiana to the Gulf of Mexico. Except for Crowley's Ridge and Commerce Hills, the remnants of an old upland, the region is broad and flat, sloping very gently to the south.

Forest Area

The counties in the north-central portion of the Riverborder Unit (Osage, Gasconade, Warren, Franklin, Jefferson, and Ste. Genevieve) remain the most heavily forested (fig. 1). Even though these counties comprise only 29 percent of the Unit's total area, they contain 51 percent of the forest cover.

The 2.1 million acres of timberland reported in 1989 are essentially equal to the area reported in 1972. Ste. Genevieve was the only county to gain more than 20 thousand acres of timberland, having an increase of more than 15 percent in timberland area between inventories. St. Louis and Osage were the only counties to lose more than 20 thousand acres. Osage County lost about 15 percent of its timberland and St. Louis County lost about half of its.

Reserved forest land increased more than 45 thousand acres between surveys. The reason for this increase was the addition of lands to Missouri Department of Conservation State parks

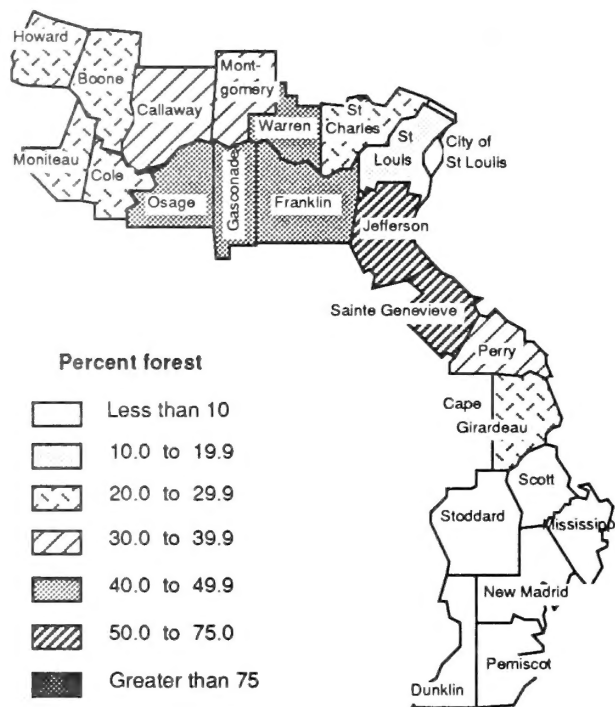

Figure 1.—Percent forest land by county, Riverborder.

and natural areas, various county and municipal parks and recreation areas, and U.S. Army Corps of Engineers recreation areas. Much of the 37 thousand acres of timberland lost in St. Louis County went into county parks. The 1972 inventory showed less than 3 thousand acres of reserved land in St. Louis County; in 1989 more than 25 thousand acres were found. Some of these areas, mainly smaller county parks and natural areas outside of state parks, may have existed in 1972 but were included in timberland in the 1972 report. In the 1989 inventory every effort was made to account for all areas of reserved forest land. All forested areas designated as public use recreation areas where tree removals are only for recreational facility improvement or safety were classified as reserved forest land. This classification is not imposed by the Corp of Engineers, which rarely precludes commercial timber management from any forested area. All designated recreation areas have been classified as reserved to maintain

consistency with other public recreation areas such as State, county, and municipal parks where commercial timber harvesting is restricted.

Eighty-five percent of the timberland area is held by non-industrial private owners (fig. 2). These are private owners who do not operate wood processing plants. Public agencies own only 6 percent of the timberland; the Missouri Department of Conservation is the largest public owner.

Figure 2.—Area of timberland by owner class, 1989.

The white oak forest type (650 thousand acres) and the black-scarlet oak type (519 thousand acres) still dominate the Unit's timberland base. A gain in the area of sawtimber size stands (currently 1.3 million acres) indicates the continuing net growth of the forests.

Volume

Volume of growing stock totaled 1.7 billion cubic feet in 1989, or 833 cubic feet per acre.

Oak species account for 60 percent (1.05 billion cubic feet) of the growing-stock volume in the Unit (fig. 3).

Figure 3.—Volume of growing stock by major species group.

Many trees in Missouri have short boles and poor form because they developed in the open conditions following the early clearing of the forest and use of the land for farming. This history has resulted in forests with low volumes per acre and poor form. One third of the total net volume of live hardwood trees is in cull trees (fig. 4). If the usable volume of all short-log and rough trees were included, volume per acre in the Riverborder would jump from 833 cubic feet per acre for growing stock to 1,172 cubic feet per acre.

Sawtimber volume (the volume of large, growing-stock trees) totaled 5.61 billion board feet in 1989 or 2,682 board feet per acre.

Forty-eight percent (2.5 billion board feet) of hardwood sawtimber volume is in trees 11 to 15 inches d.b.h., 39 percent (2.1 billion board feet) is in trees 15 to 21 inches d.b.h., and 13 percent (0.7 billion board feet) is in trees more than 21 inches d.b.h. (fig. 5).

Figure 4.—Distribution of all live volume of hardwood species by tree class.

Figure 5.—Hardwood sawtimber volume by species group and diameter class.

Species of white oaks contain the most sawtimber with just over 2.2 billion board feet; red oak species are second with 1.2 billion board feet. One third of the softwood sawtimber is eastern redcedar. Eastern redcedar trees less than 13 inches d.b.h. account for about half (204 million board feet) of the total softwood sawtimber in the Riverborder.

Stand Conditions and Timber Use

More than half of the timberland in the Unit is capable of growing 50 cubic feet or more of wood per acre per year, but actual growth is well below this capability. Net growth of growing stock totaled 44.3 million cubic feet in 1988 or 21.2 cubic feet per acre per year. Sawtimber growth totaled 196 million board feet in 1988. Under proper management and protection, growth on these lands can be increased.

Growing-stock mortality averaged 16.1 million cubic feet per year between surveys or 0.9 percent of inventory. Of the species groups having more than 10 million cubic feet of growing stock, willow and elm were the only two in which mortality exceeded 2.0 percent of inventory. Very little cutting of any willows (leaving them to die of natural causes) and Dutch elm disease are the most likely reasons for the high mortality rates in these two species.

Annual removals of growing stock averaged 21.2 million cubic feet per year between inventories, only 48 percent of current net annual growth (44.3 million cubic feet) in the Unit. The low removals and mortality rates of softwoods (fig. 6) relative to growth are an indication of the young vigorous stands not yet being harvested. Only 49 percent of the area in softwood forest types (shortleaf pine, eastern redcedar and eastern redcedar-hardwood) are of sawtimber size; 64 percent of the area in the hardwood forest types is in sawtimber stands.

Figure 6.—Annual growth, removals, and mortality of growing stock on timberland by major species group.

APPENDIX

ACCURACY OF SURVEY

Forest Inventory and Analysis information is based on a sampling procedure designed to provide reliable statistics at the State and Survey Unit levels. Consequently, the reported figures are estimates only. A measure of reliability of these figures is given by sampling errors. These sampling errors mean that the chances are two out of three that if a 100-percent inventory had been taken, using the same methods, the results would have been within the limits indicated.

For example, the estimated growing-stock volume in the Unit in 1989, 1,742.7 million cubic feet, has a sampling error of ± 2.7 percent (± 47.1 million cubic feet). The growing-stock volume from a 100-percent inventory would be expected to fall between 1,789.8 and 1,695.6 million cubic feet ($1,742.7 \pm 47.1$), there being a one in three chance that this is not the case.

The following tabulation shows the sampling errors for the 1989 Riverborder Forest Inventory:

Item	Unit totals	Sampling error
Growing stock	(Million cubic feet)	(Percent)
Volume (1989)	1,742.7	2.7
Growth (1988)	44.3	5.2
Average annual removals (1972-1988)	21.2	23.5
Sawtimber	(Million board feet)	
Volume (1989)	5,199.6	3.6
Growth (1988)	195.9	4.8
Average annual removals (1972-1988)	79.0	29.1
Timberland	(Thousand acres)	
Area (1989)	2,092.7	1.5

As survey data are broken down into sections smaller than Survey Unit totals, the sampling error increases. For example, the sampling error for timberland area in a particular county is higher than that for total timberland area in the Unit. This tabulation shows the sampling errors for Unit totals. To use this information for data smaller than Unit totals, use the following formula to compute error estimates:

$$E = \frac{(SE) \sqrt{(\text{Unit total area or volume})}}{\sqrt{(\text{Volume or area smaller than Unit total})}}$$

where:

E = sampling error in percent
SE = Unit total error for area or volume

For example, to compute the error on the area of timberland in the black-scarlet oak type in the Unit, proceed as follows:

The total area of black-scarlet oak type in the Unit from table 3 = 518,700 acres

The total area of all timberland in the Unit from table 3 = 2,092,700 acres

The Unit total error for timberland area from the above tabulation = 1.5 percent

Using the above formula:

$$\begin{aligned} \text{Error} &= \frac{(1.5) \sqrt{2,092,700}}{\sqrt{518,700}} \\ &= \pm 3.01 \text{ percent} \end{aligned}$$

SURVEY PROCEDURES

The 1989 Missouri survey used a growth model-enhanced, two-phase sample design. This sampling scheme and associated estimators are similar to sampling with partial replacement (SPR), in that a set of randomly located plots is available for remeasurement and a random set of new plots is established and measured. A significant feature of the new Missouri design is stratification for disturbance on the old sample and use of a growth model to improve regression estimates made on old undisturbed forest plots (fig. 7). The growth model used in the Missouri survey design was the Central States Stand and Tree Evaluation and Modeling System (STEMS)¹.

These were the major steps in the new survey design:

1. Aerial photography (Phase 1)

In this phase two sets of random points were located on current aerial photography. The first is a set of new photo plots and the second is a set of relocated old photo plots (ground plot locations from the previous inventory). Photos were 1:20,000 and 1:40,000 scale black and white panchromatic prints provided by the Agricultural Stabilization and Conservation Service and the Missouri Department of Natural Resources Geology and Land Survey. The year of photography for each county in the Unit is shown below.

¹ Shifley, S.F. 1987. A generalized system of models forecasting central states tree growth. Res. Pap. NC-279. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station. 10 p.

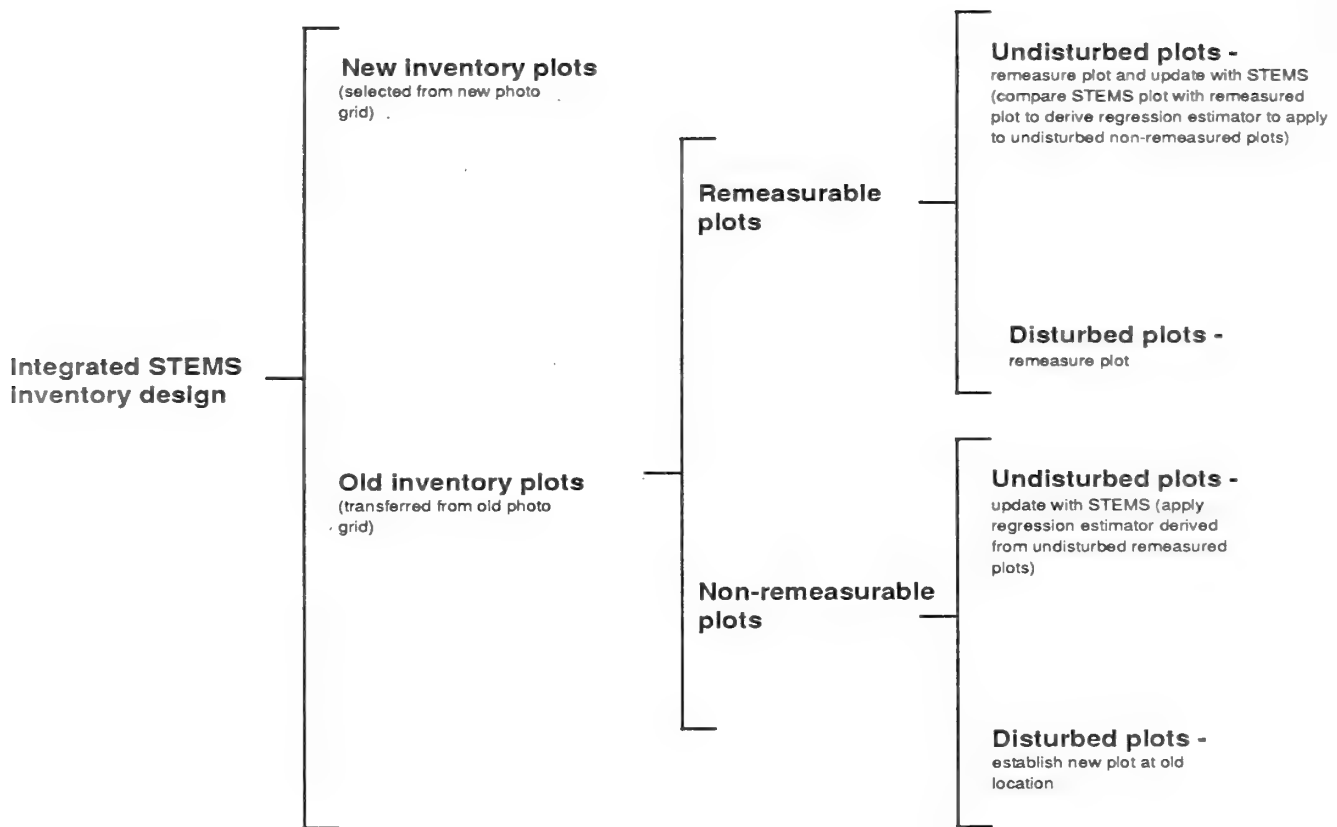

Figure 7.—Overview of the Missouri sample design.

County	Date	County	Date	County	Date
Boone	1977	Jefferson	1979	St. Charles	1980
Callaway	1982	Mississippi	1981	St. Louis	1980
Cape Girardeau	1981	Moniteau	1981	Ste. Genevieve	1981
Cole	1981	Montgomery	1979	Scott	1981
Dunklin	1981	New Madrid	1981	Stoddard	1981
Franklin	1980	Osage	1981	Warren	1980
Gasconade	1979	Pemiscot	1981	City of St. Louis	1980
Howard	1981	Perry	1981		

The locations of the plots used in the 1972 inventory were transferred to these new photographs. The photographs were then assembled into township mosaics, and a systematic grid of 121 one-acre photo plots (each plot representing approximately 190.4 acres) was overlaid on each township mosaic. Each of these plots (both the new systematic grid points and the old sample plots) was examined by aerial photogrammetrists

and classified stereoscopically based on land use. If trees were present, forest type and stand size-density class were recorded. Then all the old sample locations and a sample of the new photo plots were sent to the field for the field crew to verify the photo classification and to take further measurements. A total of 43,411 photo plots (40,849 new and 2,562 old) was examined stereoscopically:

Photo land class	Photo plots
Timberland	12,128
Reserved timberland	279
Questionable	52
Nonforest with trees	1,029
Nonforest without trees	29,257
Water	<u>666</u>
All classes	43,411

2. Plot measurements (Phase 2)

On plots classified as timberland, wooded pasture, or windbreak (at least 120 feet wide), a ground plot was established, remeasured, or modelled. Ground plots consist of a 10-point cluster covering approximately 1 acre. At each point, trees 5.0 inches or more in d.b.h. were sampled on a 37.5 Basal Area Factor (BAF) variable-radius plot, and trees less than 5.0 inches d.b.h. were sampled on a 1/300-acre fixed-radius plot.

From the new photo plots, a random sample of ground plots was established, and measures of land use, volume, mortality, and cutting were recorded. These locations were monumented for future remeasurement. The procedures for the old inventory photo plots (old plot locations) were somewhat different. Old plots were classed as remeasurable (monumented) or nonremeasurable (not monumented and thus difficult to relocate in the field). Within both of these groups, old plots can additionally be identified as undisturbed or disturbed. Ground plots corresponding to remeasurable old inventory photo plots that were classified as undisturbed forest land were remeasured to obtain current land use, volume, growth and removals information.

All undisturbed remeasurable forest plots were projected to the current time using STEMS, which yields projected estimates of current volume and growth. The comparison of the projected and observed values for these plots provided local calibration data to adjust the projected values of the undisturbed nonremeasurable plots. The adjustment procedure is

described by Smith² in a separate publication. All disturbed remeasurable plots were remeasured on the ground to assess changes since the last inventory. Disturbance refers to any change on a plot that can be detected on aerial photos and that the STEMS growth processor cannot predict, such as catastrophic mortality, cutting, seedling stands, and land use change.

Nonremeasurable forest plots were not monumented during the 1972 inventory, but play a crucial role in the new survey design. These points were carefully examined, comparing past and current aerial photography to determine which plots were undisturbed and had conditions that could be simulated by STEMS. For those plots that could be updated, past and current photography was examined to determine that only normal growth and mortality had occurred. STEMS was then used to "grow" the old plot and tree data to produce an estimate of current data. Thus, these plots were treated as ground plots, even though they were never visited. The plot record for each updated plot was sent to the field for verification of current ownership information. For plots classified as disturbed, a new ground plot was established as close to the old location as possible. This allows information about land use trend to be recorded even though it may not be possible to locate the old plot exactly.

The estimation procedure for computing statistics from this sampling design was more complicated than the simple two-phase estimation procedure used in the past. In fact, this procedure yielded two independent samples, one coming from the new photo points and the other from the old photo points that are remeasured or updated. The following tabulation summarizes the distribution of ground plots for the new inventory design:

² Smith, W. Brad. 1983. *Adjusting the STEMS regional growth models to improve local predictions*. Res. Note NC-297. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station. 5 p.

Ground land use class	Old plots remeasured	Old plots updated	Old plots replaced	New plots	Total plots
Timberland	329	50	70	226	675
Reserved timberland	4	0	0	29	33
Woodland	6	0	3	14	23
Reserved woodland	0	0	0	0	0
Nonforest with trees	17	11	10	39	77
Nonforest without trees	44	1,842	53	508	2,447
Water	1	37	0	19	57
Total	401	1,940	136	835	3,312

3. Area estimates

Area estimates were made using two-phase estimation methods. In this type of estimation, a preliminary estimate of area by land use is made from the aerial photographs (phase 1) and corrected by the plot measurements (phase 2). A complete description of this estimation method is presented by Loetsch and Haller³.

4. Volume estimates

Estimates of volume per acre were made from the trees measured or modelled on the 10-point plots. Estimates of volume per acre were multiplied by the area estimates to obtain estimates of total volume. Net cubic foot volumes are based on equations developed by Hahn and Hansen⁴ for use in the Central States.

The Forest Service reports all board foot volume in International 1/4-inch rule. In Missouri, the Doyle log rule is commonly used. Doyle log rule

conversion factors were derived from full tree measurements taken throughout the Central States (Illinois, Indiana, Iowa, and Missouri) and an equation developed by Wiant and Castenaeda⁵. The factors (multipliers) for converting board foot International volumes to the Doyle rule are shown in the following tabulation:

D.b.h. (Inches)	Doyle rule conversion factor	
	Softwoods	Hardwoods
9.0-10.9	0.3455	—
11.0-12.9	0.4780	0.4172
13.0-14.9	0.5992	0.5118
15.0-16.9	0.6908	0.5882
17.0-18.9	0.7685	0.6569
19.0-20.9	0.8573	0.7180
21.0-22.9	0.8645	0.7829
23.0-24.9	0.9276	0.8324
25.0-26.9	0.9493	0.8736
27.0-28.9	0.9710	0.9473
29.0+	1.1065	1.1349

⁴Hahn, Jerold T.; Hansen, Mark H. (In prep.). *Tree volume equations for the Central States*. Res. Pap. NC-. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station.

⁵Wiant, Harry V., Jr.; Castenaeda, Froylan. 1977. *Me-savage and Girard's volume tables formulated*. BLM4. Denver, CO: U.S. Department of Interior, Bureau of Land Management, Denver Service Center: 1-4.

5. Growth and mortality estimates

On remeasured plots, estimates of growth and mortality per acre come from the remeasured diameters of trees and from observation of trees that died between inventories. Growth is reported for 1988, the last year before the inventory, and is based on an assumption of constant basal area growth over the remeasurement period. Mortality is reported for 1988 also, and is based on an assumption of constant volume mortality over the remeasurement period. On new plots, where trees were not remeasured, estimates of growth and mortality were obtained by using STEMS to project the growth and mortality of trees for 1 year. Growth and mortality estimates for old undisturbed plots that were updated were derived in the same manner as remeasured plots. The STEMS growth model was adjusted by Survey Unit to meet local conditions. As with volume, total growth and mortality estimates were obtained by multiplying the per acre estimates by area estimates.

6. Average annual removals estimates

Average annual growing-stock and sawtimber removals (1972 to 1988) were estimated only from the remeasured plots; new plots were not used to estimate removals. These estimates are obtained from trees measured in the last survey and cut or otherwise removed from the timberland base. Because remeasurement plots make up about one-half of the total ground plots, average annual removals estimates have greater sampling errors than volume and growth estimates.

COMPARING RIVERBORDER FOURTH INVENTORY WITH THE THIRD INVENTORY

The following paragraphs highlight some of the procedural changes since the last inventory and are provided to assist the reader in analyzing data from this report:

New volume equations were developed for the Central States, and these equations were used to compute the 1989 volumes and also to recompute the 1972 volume for growth calculations. Although the adjustment varies by Survey Unit, the recomputed 1972 growing-stock and board foot volumes will generally be greater than those shown in the 1972 report.

Mortality figures published in the 1972 inventory report were based on field estimates from a limited number of remeasurement plots. Information gathered on a larger number of remeasurement plots during the current inventory was used to adjust the 1972 mortality figures. This adjustment will also affect the estimate of net growth for the 1972 inventory.

Past surveys used only growing-stock trees to determine stand-size class. Current survey procedures require that stand-size class be determined on the basis of all live trees. Therefore, direct comparisons of current inventory data to old inventory data by stand-size class may be misleading.

The basic building block for estimating forest area and timber volume has been changed from the Survey Unit to the county. In the past, the statistics were developed at the Unit level and prorated back to the county on the basis of photo-interpretation points. Direct development of county-level data helps users interested in more precise local data, but can make the outcome of comparisons with past estimates uncertain.

LOG GRADE

In Missouri the butt log of every sawtimber sample tree was graded for quality on approximately one-third of the sample plots. The volume yield by log grade for species in this sample was used to distribute the volume of trees in the ungraded sample into log-grade classes by species group.

Logs were graded on the basis of external characteristics as indicators of quality. Hardwood species were graded according to "A guide to hardwood log grading"⁶. The best 12-foot section of the lowest 16-foot hardwood log, or the best 12-foot upper section if the butt log did not meet minimum log-grade standards, was graded as follows:

⁶Rast, Everette D.; Sonderman, David L.; Gammon, Glenn L. 1973. *A guide to hardwood log grading*. Gen. Tech. Rep. NE-1. Upper Darby, PA: U.S. Department of Agriculture, Forest Service, Northeastern Forest Experiment Station. 31 p.

Forest Service standard grades for hardwood factory saw logs

Grading factors		Specifications							
		Log grade 1			Log grade 2				Log grade 3
		Butts only	Butts & uppers		Butts & uppers				Butts & uppers
Position in tree									
Scaling diameter, inches		13-15 ¹	16-19	20+	11+ ²	12+			8+
Length without trim, feet			10+		10+	8-9	10-11	12+	8+
Required clear cuttings ³ of each of three best faces ⁴	Min. length, feet	7	5	3	3	3	3	3	2
	Max. number	2	2	2	2	2	2	3	No limit
	Min. proportion of log length required in clear cutting	5/6	5/6	5/6	2/3	3/4	2/3	2/3	1/2
Maximum sweep & crook allowance	For logs with less than one-fourth of end in sound defects		15 percent				30 percent		50 percent
	For logs with more than one-fourth of end in sound defects		10 percent				20 percent		35 percent
Maximum scaling deduction			40 percent ⁵				50 percent ⁶		50 percent

¹ Ash and basswood butts can be 12 inches if they otherwise meet requirements for small #1's.

² Ten-inch logs of all species can be #2 if they otherwise meet requirements for small #1's.

³ A clear cutting is a portion of a face, extending the width of the face, that is free of defects.

⁴ A face is one-fourth of the surface of the log as divided lengthwise.

⁵ Otherwise #1 logs with 41- to 60-percent deductions can be #2.

⁶ Otherwise #2 logs with 51- to 60-percent deductions can be #3.

Forest Service standard specifications for hardwood construction logs (tie and timber logs)¹

Position in tree	Butts and uppers
Min. diameter, small end	8 inches +
Min. length without trim	8 feet
Clear cuttings	No requirements
Sweep allowance	One-fourth of the diameter at the small end for each 8 feet of length.

Sound surface defects:

Single knots	Any number, if no one knot has an average diameter above the callus in excess of one-third of the log diameter at point of occurrence.
Whorled knots	Any number, if the sum of knot diameters above the callus does not exceed one-third of the log diameter at point of occurrence.
Holes	Any number provided none has a diameter over one-third of the log diameter at point of occurrence, and none extends more than 3 inches into included timber ² .

Unsound surface defects :	Same requirements as for sound defects if they extend into included timber. No limit if they do not.
---------------------------	--

End defects:

Sound	No requirements.
Unsound	None allowed; log must be sound internally, but will admit one shake not to exceed one-fourth the scaling diameter and will admit one longitudinal split not extending more than 5 inches into included timber.

¹These specifications are minimum for the class. If, from a group of logs, factory logs are selected first, thus leaving only nonfactory logs from which to select construction logs, then the quality range of the construction logs so selected is limited, and the class may be considered a grade. If selection for construction logs is given first priority, it may be necessary to subdivide the class into grades.

²Included timber is always square, and dimension is judged from small end.

Log grades for southern pine logs

Grade 1: logs with three or four clear faces¹ and 16 inches minimum d.i.b.

Grade 2: logs with one or two clear faces and 12 inches minimum d.i.b.

Grade 3: logs with no clear faces and 6 inch minimum d.i.b.

After the tentative log grade is established from above, the log will be degraded one grade for each of the following, except that no log can be degraded below grade 3. Net scale after deduction for defect must be at least 50 percent of the gross contents of the log.

1. *Sweep.* Degrade any tentative 1 or 2 log one grade if sweep amounts to 3 or more inches and equals or exceeds one-third of the diameter inside bark at small end.
2. *Heart rot.* Degrade any tentative 1 or 2 log one grade if conk, massed hyphae, or other evidence of advanced heart rot is found anywhere in it.

¹A face is one-fourth of the circumference in width extending full length of the log. Clear faces are those free of: knots measuring more than 1 inch in diameter, overgrown knots of any size, and holes more than one inch in diameter. Faces may be rotated to obtain the maximum number of clear ones.

Log grades for eastern redcedar (Missouri special use)

Position in tree	Butts and uppers
D.B.H.	6 inches +
Min. diameter(ob), small end	5 inches +
Length without trim	7 feet
Clear cuttings	No requirements
Sweep allowance	Reasonably straight

Sound surface defects permitted:

Single knot	Any number less than one-half of the log diameter at point of occurrence.
Whorled knots	Any number provided the sum of the diameter of knots 2 inches or larger in a 1-foot section does not exceed the diameter at that point.

Unsound defects permitted:	Any number, provided defect is not greater than one-half of the volume at any one point of occurrence.
----------------------------	--

METRIC EQUIVALENTS OF UNITS USED IN THIS REPORT

1 acre = 4,046.86 square meters or 0.405 hectare.
 1,000 acres = 405 hectares.
 1 cubic foot = 0.0283 cubic meter.
 1 foot = 30.48 centimeters or 0.3048 meter.
 1 inch = 25.4 millimeters, 2.54 centimeters, or 0.0254 meter.
 1 pound = 0.454 kilograms.
 1 ton = 0.907 metric tons.

TREE SPECIES GROUPS IN MISSOURI⁷

SOFTWOODS

Shortleaf pine *Pinus echinata*
Virginia pine *Pinus virginiana*
Baldcypress *Taxodium distichum*
Eastern redcedar *Juniperus virginiana*
Other softwoods

Scotch pine*Pinus sylvestris*

HARDWOODS

Select white oak⁸

White oak.....	<i>Quercus alba</i>
Swamp white oak	<i>Quercus bicolor</i>
Bur oak	<i>Quercus macrocarpa</i>
Swamp chestnut oak	<i>Quercus michauxii</i>
Chinkapin oak	<i>Quercus muehlenbergii</i>

Other white oak⁸

Overcup oak *Quercus lyrata*
Chestnut oak *Quercus prinus*
Post oak *Quercus stellata*

Select red oak⁸

Cherrybark oak *Quercus falcata*
var. *pagodifolia*
Northern red oak *Quercus rubra*
Shumard oak..... *Quercus shumardii*
var. *shumardii*

Other red oak⁸

Scarlet oak *Quercus coccinea*
 Northern pin oak *Quercus ellipsoidalis*
 Southern red oak *Quercus falcata*
 Shingle oak *Quercus imbricaria*
 Black oak *Quercus velutina*
 Blackjack oak *Quercus marilandica*
 Pin oak *Quercus palustris*
 Willow oak *Quercus phellos*

Select hickory⁸

Pecan *Carya illinoensis*
 Shellbark hickory *Carya laciniosa*
 Shagbark hickory *Carya ovata*
 Mockernut hickory *Carya tomentosa*

⁷ The common and scientific names are based on: Little, Elbert L. 1979. Checklist of native and naturalized trees of the United States. Agric. Handb. 541. Washington, DC: U.S. Department of Agriculture, Forest Service. 375 p.

⁸ This species or species group is considered a hard hardwood, with an average specific gravity greater than or equal to 0.50.

Other hickory⁸

Bitternut hickory.....*Carya cordiformis*
 Pignut hickory*Carya glabra*
 Black hickory*Carya texana*
 River birch⁸.....*Betula nigra*

Hard maple⁸

Sugar maple*Acer saccharum*
Soft maple⁹
Red maple*Acer rubrum*
Silver maple*Acer saccharinum*

Ash⁸

Blue ash	<i>Fraxinus quadrangulata</i>
White ash	<i>Fraxinus americana</i>
Green ash	<i>Fraxinus pennsylvanica</i>
Cottonwood ⁹	<i>Populus deltoides</i>
Basswood ⁹	<i>Tilia americana</i>
Beech ⁸	<i>Fagus grandifolia</i>
Black walnut ⁸	<i>Juglans nigra</i>
Black cherry ⁹	<i>Prunus serotina</i>
Butternut ⁹	<i>Juglans cinerea</i>
Elm	

Winged elm⁹ *Ulmus alata*
 American elm⁹ *Ulmus americana*
 Slippery elm⁹ *Ulmus rubra*
 Rock elm⁸ *Ulmus thomasi*
 Hackberry⁹ *Celtis occidentalis*
 Sycamore⁹ *Platanus occidentalis*
 Yellow-poplar⁹ *Liriodendron tulipifera*
 Black willow⁹ *Salix nigra*
 Sweetgum⁹ *Liquidambar styraciflua*
 Tupelo⁹

Black tupelo*Nyssa sylvatica*
var. *sylvatica*
Swamp tupelo*Nyssa sylvatica*
var. *biflora*

Persimmon⁸ *Diospyros virginiana*
Sassafras⁹ *Sassafras albidum*

Other hardwoods

Ohio buckeye⁹ *Aesculus glabra*
 Boxelder⁹ *Acer negundo*
 Kentucky coffeetree⁸ *Gymnocladus dioica*
 Black locust⁸ *Robinia pseudoacacia*
 White mulberry⁹ *Morus alba*
 Red mulberry⁹ *Morus rubra*
 Honeylocust⁸ *Gleditsia triacanthos*
 Northern catalpa⁸ *Catalpa speciosa*

⁹ This species or species group is considered a soft hardwood, with an average specific gravity of 0.50 or less.

Noncommercial species

Osage-orange	<i>Maclura pomifera</i>
Eastern hophornbeam	<i>Ostrya virginiana</i>
Apple	<i>Malus</i> spp.
American hornbeam	<i>Carpinus caroliniana</i>
Wild plum	<i>Prunus</i> spp.
Eastern redbud	<i>Cercis canadensis</i>
Pawpaw	<i>Asimina triloba</i>
Hawthorn	<i>Crataegus</i> spp.

DEFINITION OF TERMS

Average annual removals from growing stock.

—The average net growing-stock volume in growing-stock trees removed annually for forest products (including roundwood products and logging residues) and for other uses (see Other removals). Average annual removals of growing stock are reported for a period of several years (1972 to 1988 in this report) and are based on information obtained from remeasurement plots (see Survey Procedures in Appendix).

Average annual removals from sawtimber.—

The average net board foot sawtimber volume of live sawtimber trees removed annually for forest products (including roundwood products and other uses [see Other removals]). Average annual removals of sawtimber are reported for a period of several years (1972 to 1988 in this report) and are based on information obtained from remeasurement plots (see Survey Procedures in Appendix).

Basal area.—

The area in square feet of the cross section at breast height of a single tree. When the basal area of all trees in a stand is summed, the result is usually expressed as square feet of basal area per acre.

Commercial species.—Tree species presently or prospectively suitable for industrial wood products. (Note: Excludes species of typically small size, poor form, or inferior quality such as hophornbeam, osage-orange, and redbud.)

Commercial forest land.—(See Timberland).

Cord.—One standard cord is 128 cubic feet of stacked wood, including bark and air space. Cubic feet can be converted to standard cords by dividing by 79.

County and municipal land.—Land owned by counties and local public agencies or municipalities, or land leased to these governmental units for 50 years or more.

Cropland.—Land under cultivation within the past 24 months; including cropland harvested, crop failures, cultivated summer fallow, idle cropland used only for pasture, orchards, and land in soil improvement crops, but excluding land cultivated in developing improved pasture.

Cull.—Portions of a tree that are unusable for industrial wood products because of rot, missing or dead material, or other defect.

Diameter class.—A classification of trees based on diameter outside bark, measured at breast height (d.b.h.). Two-inch diameter classes are commonly used in Forest Inventory and Analysis, with the even inch the approximate midpoint for a class. For example, the 6-inch class includes trees 5.0 through 6.9 inches d.b.h.

Diameter at breast height (d.b.h.).—The outside bark diameter at 4.5 feet (1.37 m) above the forest floor on the uphill side of the tree. For determining breast height, the forest floor includes the duff layer that may be present, but does not include unincorporated woody debris that may rise above the ground line.

Farm.—Any place from which \$1,000 or more of agricultural products were produced and sold during the year.

Farmer-owned land.—Land owned by farm operators whether part of the farmstead or not. (Note: Excludes land leased by farm operators from nonfarm owners, such as railroad companies and States.)

Forest land.—Land at least 16.7 percent stocked by forest trees of any size, or formerly having had such tree cover, and not currently developed for nonforest use. (Note: Stocking is measured by comparing specified standards with basal area and/or number of trees, age or size, and spacing.) The minimum area for classification of forest land is 1 acre. Roadside, streamside, and shelterbelt strips of timber must have a crown width of at least 120 feet to qualify as forest land. Unimproved roads and trails, streams, or other bodies of water or clearings in forest areas shall be classed as forest if less than 120 feet wide. (See Tree, Land, Timberland, Reserved forest land, Other forest land, Stocking, and Water.)

Forest industry land.—Land owned by companies or individuals that operate a primary wood-using plant.

Forest type.—A classification of forest land based on the species forming a plurality of live tree stocking. Major forest types in the State are:

Shortleaf pine.—Forests in which shortleaf pine comprises a plurality of the stocking. (Common associates include oak, hickory, and gum.)

Eastern redcedar.—Forests in which eastern redcedar comprises a plurality of the stocking. (Common associates include oak and hickory.)

Eastern redcedar-hardwood.—Forests in which hardwoods (usually upland oaks), comprise a plurality of the stocking but where eastern redcedar comprises 25 to 50 percent of the stocking. (Common associates include gum, hickory, and yellow-poplar.)

Shortleaf pine-oak.—Forests in which hardwoods (usually white, scarlet, chestnut, northern red, or black oaks), singly or in combination, comprise a plurality of the stocking but where shortleaf pine comprises 25 to 50 percent of the stocking.

Post-blackjack oak.—Forests in which post or blackjack oaks, singly or in combination, comprise a plurality of the stocking, and less than 25 percent of the stocking is in pines or eastern redcedar.

Black-scarlet oak.—Forests in which black oak or scarlet oaks, singly or in combination, comprise a plurality of the stocking, and less than 25 percent of the stocking is in pines or eastern redcedar. (Common associates include yellow-poplar, elm, maple, and black walnut.)

White oak.—Forests in which white oak species, singly or in combination, comprise a plurality of the stocking, and less than 25 percent of the stocking is in pines or eastern redcedar.

Oak-gum-cypress.—Bottomland forests in which bottomland oaks such as pin, swamp white, and shingle oaks along with tupelo, blackgum, sweetgum, or cypress, singly or in combination, comprise a plurality of the stocking. (Common associates include cottonwood, willow, ash, elm, hackberry, and maple.)

Elm-ash-soft maple.—Forests in which lowland elm, ash, soft maple, and cottonwood, singly or in combination, comprise a plurality of the stocking. (Common associates include boxelder, willow, sycamore, and beech.)

Cottonwood.—Forests in which cottonwood comprises at least 50 percent of the stocking. (Associates include willow, elm, soft maple, and ash.)

Maple-beech.—Forests in which hard maple or beech, singly or in combination, comprises a plurality of the stocking. (Common associates include soft maple, elm, and basswood.)

Growing-stock tree.—A live tree of commercial species that meets specified standards of size, quality, and merchantability. (Note: Excludes rough, rotten, and dead trees.)

Growing-stock volume.—Net volume in cubic feet of growing-stock trees 5.0 inches d.b.h. and over, from 1 foot above the ground to a minimum 4.0-inch top diameter outside bark of the central stem or to the point where the central stem breaks into limbs.

Hard hardwoods.—Hardwood species with an average specific gravity greater than 0.50 such as oaks, hard maple, hickories, and ash.

Hardwoods.—Dicotyledonous trees, usually broad-leaved and deciduous. (See Soft hardwoods and Hard hardwoods.)

Idle farmland.—Includes former cropland, orchards, improved pastures, and farm sites not tended within the past 2 years and presently less than 16.7 percent stocked with trees.

Improved pasture.—Land currently improved for grazing by cultivating, seeding, irrigating, or clearing of trees or brush and less than 16.7 percent stocked with live trees.

Industrial wood.—All roundwood products, except fuelwood.

Land.—A. *Bureau of the Census.* Dry land and land temporarily or partly covered by water such as marshes, swamps, and river flood plains (omitting tidal flats below mean high tide); streams, sloughs, estuaries, and canals less than one-eighth of a statute mile wide; and lakes, reservoirs, and ponds less than 40 acres in area.

B. *Forest Inventory and Analysis.* The same as the Bureau of the Census, except minimum width of streams, etc., is 120 feet and minimum size of lakes, etc., is 1 acre.

Log grade.—A log classification based on external characteristics as indicators of quality or value. (See Appendix for specific grading factors used.)

Marsh.—Nonforest land that characteristically supports low, generally herbaceous or shrubby vegetation and that is intermittently covered with water.

Merchantable.—Refers to a pulpwood or saw-log section that meets pulpwood or saw-log specifications, respectively.

Miscellaneous Federal land.—Federal land other than National Forest and land administered by the Bureau of Land Management or Bureau of Indian Affairs.

Miscellaneous private land.—Privately owned land other than forest-industry and farmer-owned land.

Mortality.—The volume of sound wood in growing-stock and sawtimber trees that die annually.

National Forest land.—Federal land that has been legally designated as National Forest or purchase units, and other land administered by the USDA Forest Service.

Net annual growth of growing stock.—The annual change in volume of sound wood in live sawtimber and poletimber trees and the total volume of trees entering these classes through ingrowth, less volume losses resulting from natural causes.

Net annual growth of sawtimber.—The annual change in the volume of live sawtimber trees and the total volume of trees reaching sawtimber size, less volume losses resulting from natural causes.

Net volume.—Gross volume less deductions for rot, sweep, or other defect affecting use for timber products.

Noncommercial species.—Tree species of typically small size, poor form, or inferior quality that normally do not develop into trees suitable for industrial wood products.

Nonforest land.—Land that has never supported forests, and land formerly forested where use for timber management is precluded by development for other uses. (Note: Includes areas used for crops, improved pasture, residential areas, city parks, improved roads of any width and adjoining clearings, power-line clearings of any width, and 1- to 40-acre areas of water classified by the Bureau of the Census as land. If intermingled in forest areas, unimproved roads and nonforest strips must be more than 120 feet wide and more than 1 acre in area to qualify as nonforest land.)

a. *Nonforest land without trees.*—Nonforest land with no live trees present.

b. *Nonforest land with trees.*—Nonforest land with one or more trees per acre at least 5 inches d.b.h.

Nonstocked land.—Forest land less than 16.7 percent stocked with all live trees.

Other forest land.—Forest land not capable of producing 20 cubic feet per acre per year of industrial wood crops under natural conditions and not associated with urban or rural development. These sites often contain tree species that are not currently utilized for industrial wood production or trees of poor form, small size, or inferior quality that are unfit for industrial products. Unproductivity may be the result of adverse site conditions such as sterile soil, dry climate, poor drainage, high elevation, and rockiness. This land is not withdrawn from timber utilization.

Pasture.—Land presently used for grazing or under cultivation to develop grazing.

Pastured timberland.—Timberland for which the primary use is wood production, but is presently used for grazing.

Physiographic class.—A measure of soil and water conditions that affect tree growth on a site. The physiographic classes are:

Xeric sites.—Very dry soils where excessive drainage seriously limits both growth and species occurrence. Example: cedar barrens.

Xeromesic sites.—Moderately dry soils where excessive drainage limits growth and species occurrence to some extent. Example: dry oak ridge.

Mesic sites.—Deep, well-drained soils. Growth and species occurrence are limited only by climate.

Hydromesic sites.—Moderately wet soils where insufficient drainage or infrequent flooding limits growth and species occurrence to some extent. Example: better drained bottomland hardwood sites.

Hydric sites.—Very wet sites where excess water seriously limits both growth and species occurrence. Example: frequently flooded river bottoms and cypress swamps.

Poletimber stand.—(See Stand-size class.)

Poletimber tree.—A growing-stock tree of commercial species at least 5.0 inches d.b.h. but smaller than sawtimber size.

Reserved forest land.—Forest land withdrawn from timber utilization through statute, administrative regulation, designation, or exclusive use for Christmas tree production, as indicated by annual shearing.

Rotten tree.—A tree that does not meet regional merchantability standards because of excessive unsound cull. May include noncommercial tree species.

Rough tree.—A tree that does not meet regional merchantability standards because of excessive sound cull. May include noncommercial tree species.

Salvable dead tree.—A standing or down dead tree considered merchantable by regional standards.

Sapling.—A live tree 1.0 to 5.0 inches d.b.h.

Sapling-seedling stand.—(See Stand-size class.)

Saw log.—A log meeting minimum standards of diameter, length, and defect, including logs at least 8 feet long, sound and straight and with a minimum diameter outside bark (d.o.b.) for softwoods of 7.0 inches (9.0 inches for hardwoods) or other combinations of size and defect specified by regional standards.

Saw-log portion.—That part of the bole of sawtimber trees between the stump and the saw-log top.

Saw-log top.—The point on the bole of sawtimber trees above which a saw log cannot be produced. The minimum saw-log top is 7.0 inches d.o.b. for softwoods and 9.0 inches d.o.b. for hardwoods.

Sawtimber stand.—(See Stand-size class.)

Sawtimber tree.—A growing-stock tree of commercial species containing at least a 12-foot saw log or two noncontiguous saw logs 8 feet or longer, and meeting regional specifications for freedom from defect. Softwoods must be at least 9.0 inches d.b.h. Hardwoods must be at least 11.0 inches d.b.h.

Sawtimber volume.—Net volume of the saw-log portion of live sawtimber in board feet, International 1/4-inch rule (unless specified otherwise) from stump to a minimum 7.0 inches top d.o.b. for softwoods and a minimum 9.0 inches top d.o.b. for hardwoods.

Seedling.—A live tree less than 1.0 inch d.b.h. that is expected to survive. Only softwood seedlings more than 6 inches tall and hardwood seedlings more than 1 foot tall are counted.

Short-log (rough tree).—Sawtimber-size trees of commercial species that contain at least one merchantable 8- to 11-foot saw log but not a 12-foot saw log.

Site class.—A classification of forest lands in terms of inherent capacity to grow crops of industrial wood. The class identifies the potential growth in merchantable cubic feet/acre/year at culmination of mean annual increment of fully stocked natural stands.

Site index.—An expression of forest site quality based on the height of a free-growing dominant or codominant tree of a representative species in the forest type at age 50.

Soft hardwoods.—Hardwood species with an average specific gravity less than 0.50 such as gum, yellow-poplar, cottonwood, red maple, basswood, and willow.

Softwoods.—Coniferous trees, usually evergreen, having needles or scale-like leaves.

Stand.—A group of trees on a minimum of 1 acre of forest land that is stocked by forest trees of any size.

Stand-age class.—Age of the main stand. Main stand refers to trees of the dominant forest type and stand-size class.

Stand-size class.—A classification of stocked (see Stocking) forest land based on the size class of live trees on the area; that is, sawtimber, poletimber, or seedlings and saplings.

Sawtimber stands.—Stands with half or more of live stocking in sawtimber or poletimber trees, and with sawtimber stocking at least equal to poletimber stocking.

Poletimber stands.—Stands with half or more live stocking in poletimber and/or sawtimber trees, and with poletimber stocking exceeding that of sawtimber.

Sapling-seedling stands.—Stands with more than half of the live stocking in saplings and/or seedlings.

State land.—Land owned by States or leased to them for 50 years or more.

Stocking.—The degree of occupancy of land by trees, measured by basal area and/or the number of trees in a stand by size or age and spacing, compared to the basal area and/or number of trees required to fully utilize the growth potential of the land; that is, the stocking standard.

A stocking percent of 100 indicates full utilization of the site and is equivalent to 80 square feet of basal area per acre in trees 5.0 inches d.b.h. and larger. In a stand of trees less than 5.0 inches d.b.h., a stocking percent of 100 would indicate that the present number of trees is sufficient to produce 80 square feet of basal area per acre when the trees reach 5.0 inches d.b.h.

Stands are grouped into the following stocking classes:

Overstocked stands.—Stands in which stocking of live trees is 133 percent or more.

Fully stocked stands.—Stands in which stocking of trees is from 100.0 to 132.9 percent.

Medium stocked stands.—Stands in which stocking of trees is from 60.0 to 99.9 percent.

Poorly stocked stands.—Stands in which stocking of trees is from 16.7 to 59.9 percent.

Nonstocked areas.—Commercial forest land on which stocking of trees is less than 16.7 percent.

Timberland.—Forest land that is producing or capable of producing in excess of 20 cubic feet per acre per year of industrial wood crops under natural conditions, that is not withdrawn from timber utilization, and that is not associated with urban or rural development. Currently inaccessible and inoperable areas are included.

Tree.—A woody plant usually having one or more perennial stems, a more or less definitely formed crown of foliage, and a height of at least 12 feet at maturity.

Tree size class.—A classification of trees based on diameter at breast height, including sawtimber trees, poletimber trees, saplings, and seedlings.

Upper stem portion.—That part of the bole of sawtimber trees above the saw-log top to a minimum top diameter of 4.0 inches outside bark or to the point where the central stem breaks into limbs.

Urban and other areas.—Areas within the legal boundaries of cities and towns; suburban areas developed for residential, industrial, or recreational purposes; school yards; cemeteries; or other nonforest land not included in any other specified land use class.

Urban forest land.—Forest land closely associated with or in such proximity to urban nonforest land uses that is not likely to be managed for the production of industrial wood products on a continuing basis. Wood removed would be for land clearing, fuelwood, or aesthetic purposes. Such forest land may be associated with industrial, commercial, residential, or recreational nonforest uses. Residential subdivisions, industrial parks, golf course perimeters, airport buffer strips, and public urban parks that qualify as forest land are included.

Water.—Water Areas. Areas within a land mass persistently covered by water.

(a) *Bureau of the Census.*—Permanent inland water surfaces, such as lakes, reservoirs, and ponds at least 40 acres in area; and streams, sloughs, estuaries, and canals at least one-eighth of a statute mile wide.

(b) *Noncensus.*—Permanent inland water surfaces, such as lakes, reservoirs, and ponds from 1 to 39.9 acres in area; and streams, sloughs, estuaries, and canals from 120 feet to one-eighth of a statute mile wide.

Windbreak.—A group of trees whose primary use is to protect buildings currently in use.

Wooded pasture.—Improved pasture with more than 16.7 percent stocking in live trees but less than 25 percent stocking in growing-stock trees. Area is currently improved for grazing or there is other evidence of grazing.

Wooded strip.—An acre or more of natural continuous forest land that would otherwise meet survey standards for timberland except that it is less than 120 feet wide.

Hansen, Mark H.

1991. **Timber resource of Missouri's Riverborder.** Resour. Bull. NC-118. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station. 50 p.

Presents highlights and statistics on area, volume, growth, removals, and mortality found in the fourth forest inventory of Missouri's Riverborder.

KEY WORDS: Area, volume, growth, removals, mortality.

Our job at the North Central Forest Experiment Station is discovering and creating new knowledge and technology in the field of natural resources and conveying this information to the people who can use it. As a new generation of forests emerges in our region, managers are confronted with two unique challenges: (1) Dealing with the great diversity in composition, quality, and ownership of the forests, and (2) Reconciling the conflicting demands of the people who use them. Helping the forest manager meet these challenges while protecting the environment is what research at North Central is all about.
